- (57) **ABSTRACT**

Embodiments provide a ball throwing machine including a motor coupled to a rotary wheel and configured to rotate the rotary wheel at a rotational speed to throw a ball forward toward an athlete. A speed control module may be coupled to the motor and configured to rotate the rotary wheel, via the motor, at a first rotational speed during a fastball setting and a second rotational speed during a changeup setting. The speed control module may determine the second rotational speed based on the first rotational speed so that a ball thrown by the ball throwing machine will arrive in a target zone when the ball throwing machine is in the fastball setting and the changeup setting. In some embodiments, the speed control module may utilize resistive braking to transition the rotary wheel from the first rotational speed to the second rotational speed.

CHANGEUP CONTROLLER FOR BALL THROWING MACHINE

TECHNICAL FIELD

Embodiments herein relate to the field of ball throwing machines.

BACKGROUND

Ball throwing machines are used to throw baseballs, softballs, tennis balls and the like. For baseballs or softballs, the ball throwing machine may be used in batting practice to repeatedly throw balls to a batter which the batter attempts to hit. Some ball throwing machines can throw different types of pitches, such as fastballs, changeups, and/or curveballs. However, these ball throwing machines require physical adjustment to change the pitch type so that the pitches arrive at the batter in the proper position (e.g., the strike zone). The adjustment may require a longer pause between pitches, and/or changing the position of one or more components of the ball throwing machine. The batter may recognize the longer delay between pitches and/or see the adjustment of the machine, and this may indicate to the batter that a different pitch is coming, thereby negating the surprise element in batting practice.

BRIEF DESCRIPTION OF THE DRAWINGS

Embodiments will be readily understood by the following detailed description in conjunction with the accompanying drawings and the appended claims. Embodiments are illustrated by way of example and not by way of limitation in the figures of the accompanying drawings.

FIG. 1 illustrates a side view of a ball throwing machine in accordance with various embodiments;

FIG. 2 illustrates a perspective view of the ball throwing machine of FIG. 1;

FIG. 3 illustrates a functional block diagram of the ball throwing machine of FIG. 1;

FIG. 4 illustrates a changeup algorithm for a baseball throwing machine, in accordance with various embodiments;

FIG. 5 illustrates a changeup algorithm for a softball throwing machine, in accordance with various embodiments;

FIG. 6 illustrates a side view of a ball throwing machine having two rotary wheels, in accordance with various embodiments;

FIG. 7 illustrates a perspective view of the ball throwing machine of FIG. 6;

FIG. 8 illustrates a front view of a ball throwing machine having three rotary wheels, in accordance with various embodiments; and

FIG. 9 illustrates a perspective view of the ball throwing machine of FIG. 8.

DETAILED DESCRIPTION OF DISCLOSED EMBODIMENTS

In the following detailed description, reference is made to the accompanying drawings which form a part hereof, and in which are shown by way of illustration embodiments that may be practiced. It is to be understood that other embodiments may be utilized and structural or logical changes may be made without departing from the scope. Therefore, the following detailed description is not to be taken in a limiting

2

sense, and the scope of embodiments is defined by the appended claims and their equivalents.

Various operations may be described as multiple discrete operations in turn, in a manner that may be helpful in understanding embodiments; however, the order of description should not be construed to imply that these operations are order dependent.

The description may use perspective-based descriptions such as up/down, back/front, and top/bottom. Such descriptions are merely used to facilitate the discussion and are not intended to restrict the application of disclosed embodiments.

The terms “coupled” and “connected,” along with their derivatives, may be used. It should be understood that these terms are not intended as synonyms for each other. Rather, in particular embodiments, “connected” may be used to indicate that two or more elements are in direct physical or electrical contact with each other. “Coupled” may mean that two or more elements are in direct physical or electrical contact. However, “coupled” may also mean that two or more elements are not in direct contact with each other, but yet still cooperate or interact with each other.

For the purposes of the description, a phrase in the form “NB” or in the form “A and/or B” means (A), (B), or (A and B). For the purposes of the description, a phrase in the form “at least one of A, B, and C” means (A), (B), (C), (A and B), (A and C), (B and C), or (A, B and C). For the purposes of the description, a phrase in the form “(A)B” means (B) or (AB) that is, A is an optional element.

The description may use the terms “embodiment” or “embodiments,” which may each refer to one or more of the same or different embodiments. Furthermore, the terms “comprising,” “including,” “having,” and the like, as used with respect to embodiments, are synonymous, and are generally intended as “open” terms (e.g., the term “including” should be interpreted as “including but not limited to,” the term “having” should be interpreted as “having at least,” the term “includes” should be interpreted as “includes but is not limited to,” etc.).

With respect to the use of any plural and/or singular terms herein, those having skill in the art can translate from the plural to the singular and/or from the singular to the plural as is appropriate to the context and/or application. The various singular/plural permutations may be expressly set forth herein for sake of clarity.

In various embodiments, methods, apparatuses, and systems for a pitching machine controller are provided. In exemplary embodiments, a computing device may be endowed with one or more components of the disclosed apparatuses and/or systems and may be employed to perform one or more methods as disclosed herein.

Embodiments herein provide a speed control module for a pitching machine. The pitching machine may include one or more rotary wheels and a motor associated with each rotary wheel. The motors may cause their associated rotary wheels to rotate. The pitching machine may further include a feed structure configured to receive a ball and bring the ball into contact with a circumferential outer surface of the one or more rotary wheels. The ball may be thrown outwardly by rotation of the one or more rotary wheels.

In various embodiments, the speed control module may be coupled to the motor and configured to rotate the rotary wheel, via the motor, at a first rotational speed during a fastball setting and a second rotational speed during a changeup setting. The speed control module may determine the second rotational speed based on the first rotational speed so that a ball thrown by the ball throwing machine will

arrive in a target zone when the ball throwing machine is in the fastball setting and the changeup setting. In some embodiments, the speed control module may utilize resistive braking to transition the rotary wheel from the first rotational speed to the second rotational speed.

Referring to FIGS. 1 and 2, a ball throwing machine 100 may include a rotary wheel 102 coupled to a body portion 104 and supported on the ground by a support structure 106 (e.g., a tripod 106). In some embodiments, the rotary wheel 102 may include a pneumatic tire 105. A motor 108 may be coupled to the rotary wheel 102 and configured to rotationally drive the rotary wheel 102. The ball throwing machine 100 may further include a feed structure 110 coupled to the support structure and configured to receive a ball (not shown) and bring the ball into contact with an outer circumferential surface 112 of the rotary wheel 102. The feed structure may be configured for hand-feeding of balls by an operator, and/or may be configured to automatically feed balls periodically to the rotary wheel 102.

A pinch plate 114 may be coupled to the body portion and spaced apart from the outer circumferential surface 112 of the rotary wheel 102 at a distance less than the diameter of the ball. The pinch plate 114 may pinch the ball against the rotary wheel 102, and the rotary wheel 102 may throw the ball outwardly from the ball throwing machine 100 toward a batter (not shown).

A control box 109 may be coupled to the motor 108 and configured to control the rotational speed of the rotary wheel 102. In various embodiments, the ball throwing machine 100 may be selectively placed in a fastball setting and/or a changeup setting to throw a fastball pitch (a throw of relatively high speed) or a changeup pitch (a throw of relatively low speed), respectively. The motor 108 may rotate at a first rotational speed (i.e., a fastball rotational speed) during the fastball setting and at a second rotational speed (i.e., a changeup rotational speed) during the changeup setting. The second rotational speed may be slower than the first rotational speed. Accordingly, the ball throwing machine 100 may throw the ball with a faster speed when in the fastball setting than when in the changeup setting.

As shown in FIG. 3, the ball throwing machine 100 may include a speed control module 115. The speed control module 115 may be located in the control box 109 (as shown in FIG. 2). The speed control module 115 may be coupled to a power supply 120. The fastball control module 116 may be coupled to a power supply 120. The power supply 120 may be any suitable source of power, such as a 120 volt alternating current (AC) power source (e.g., a wall socket), a battery, and/or any other suitable power source.

In some embodiments, the speed control module 115 may include a fastball control module 116 (also referred to as a base speed control module 116) and a changeup control module 118. The speed control module 115 may further include a speed control mechanism 122, coupled to the fastball control module 116, to allow an operator to specify a fastball speed setting among a range of speeds. In some embodiments, the speed control mechanism 122 may include a potentiometer having a rotating dial. Alternatively, or additionally, the speed control mechanism 122 may include one or more buttons, a touchscreen and/or a display. When the ball throwing machine 100 is in the fastball setting, the rotational speed of the motor 108 (i.e., the first rotational speed) may be controlled by the fastball control module 116. The first rotational speed of the motor 108 may be determined by the fastball speed setting of the fastball control module 116.

In some embodiments, the fastball control module 116 and changeup control module 118 may be part of the same integrated circuit (e.g., located on the same chip). In other embodiments, the changeup control module 118 may be a separate circuit from the fastball control module 116. In some such embodiments, the changeup control module 118 may be configured to be coupled to a conventional fastball control module 116 of an existing machine.

In various embodiments, the changeup control module 118 may be switchable between an unengaged state (when the ball throwing machine 100 is in the fastball setting) and an engaged state (when the ball throwing machine 100 is in the changeup setting). When in the engaged state, the changeup control module 118 may cause the motor 108 to rotate at the second rotational speed in order to throw a changeup pitch.

In various embodiments, the second rotational speed may be determined based on a changeup algorithm 200a-b (as shown in FIGS. 4 and 5, respectively) applied by the changeup control module. Changeup algorithm 200a may be configured to determine the second rotational speed for throwing baseballs, while changeup algorithm 200b may be configured to determine the second rotational speed for throwing softballs. The changeup algorithm 200a-b may be configured so that the ball will arrive at an athlete (e.g., a batter) within a target zone (e.g., the strike zone) whether the ball throwing machine 100 is in the fastball setting or the changeup setting. The changeup algorithm 200a-b may determine the second rotational speed based at least in part on the first rotational speed. The difference between the first rotational speed and the second rotational speed may vary depending on the magnitude of the first rotational speed. This may facilitate the ball arriving at the batter within the target zone in the fastball setting and the changeup setting. For a fastball pitch of relatively high speed (e.g., 90 miles per hour (mph)), the speed difference between the first rotational speed and the second rotational speed may be greater than the speed difference for a fastball pitch of relatively low speed (e.g., 50 mph), while causing the ball to arrive within the target zone.

In some embodiments, as shown in FIGS. 4 and 5, the changeup algorithm 200a-b may include an equation that determines the second rotational speed based on the first rotational speed. For example, the changeup algorithm may include a polynomial equation (e.g., a second order polynomial equation), a power law equation, an exponential equation, and/or a logarithmic equation, although other types of equations are possible. In other embodiments (not shown), the changeup algorithm 200a-b may determine the second rotational speed based on a percentage of the first rotational speed (e.g., a linear equation). Alternatively, the changeup algorithm 200a-b may include a lookup table of values to correlate the first rotational speed with the second rotational speed. The changeup control module 118 may use the lookup table to determine the second rotational speed based on the first rotational speed.

The changeup algorithm 200a-b may vary depending on a distance setting of the ball throwing machine 100 (i.e., the distance from the ball throwing machine to the batter). In some embodiments, the distance setting may be set by the manufacturer (so that the distance setting is a constant in the changeup algorithm). In other embodiments, the distance setting may be selectively controlled by the operator.

In some embodiments, the changeup control module 118 may include a memory device having the changeup algorithm 200a and/or 200b stored thereon. In some embodiments, the changeup control module may include a memory

5

device having both the baseball changeup algorithm **200a** (as shown in FIG. 4) and the softball changeup algorithm **200b** (as shown in FIG. 5) stored thereon. The changeup control module **118** may include a switch, such as a dip switch, to selectively configure the changeup control module to use the baseball changeup algorithm **200a** or the softball changeup algorithm **200b**. The proper algorithm may be set by the manufacturer/retailer prior to delivery of the ball throwing machine **100** and/or the ball throwing machine **100** may include a switch accessible to the operator for changing between throwing baseballs and softballs.

In various embodiments, the changeup algorithm **200a-b** may be configured so that a position of the rotary wheel **102**, feed structure **110** (including pinch plate **114**), and/or other components of the ball throwing machine **100** (as shown in FIGS. 1 and 2) does not need to be changed between throwing a fastball pitch and a changeup pitch for the ball to arrive in the target zone. Accordingly, a trajectory of the ball as it leaves the outer circumferential surface **112** of the ball throwing machine **100** may be the same during the fastball setting and the changeup setting. The trajectory may be determined by the relative angle and/or position of the pinch plate **114** and the rotary wheel **102**. This may simplify the design and also facilitate changing the ball throwing machine **100** from the fastball setting to the changeup setting, and vice versa, without the batter noticing.

Although the fastball control module **116** and changeup control module **118** are shown in FIG. 3 as separate components within the speed control module **115**, in other embodiments the fastball control module **116** and changeup control module **118** may be integrated into the same component. For example, the fastball control module **118** and changeup control module **118** may be a part of the same integrated circuit.

Referring again to FIG. 3, in various embodiments, the speed control module **115** may use a resistive braking scheme to transition the motor **108** from the first rotational speed and the second rotational speed. The resistive braking scheme may allow the motor **108** to be transitioned relatively quickly from the first rotational speed to the second rotational speed, thereby facilitating changing from a fastball pitch to a changeup pitch without increasing the normal time delay between pitches. This may further prevent the batter from noticing that the changeup pitch is being thrown.

In various embodiments, the motor **108** may be an electric motor (e.g., a direct current (DC) motor or an alternating current (AC) motor). The motor **108** may receive an input signal at one or more input terminals **123**. The rotational speed of the motor **108** may be based on one or more parameters of the input signal received by the motor **108**. For example, the rotational speed of the motor **108** may be based on the voltage level of the input signal. In these embodiments, the input signal may also be referred to as the input voltage. In some embodiments, a higher input voltage may result in a higher rotational speed of motor **108** (and therefore a higher rotational speed of rotary wheel **102**). In other embodiments, another parameter of the input signal may be used to control the speed of the motor, such as current, frequency, and/or duty cycle (e.g., pulse width modulation) of the input signal.

In various embodiments, the fastball control module **116** may produce a first voltage (i.e., a fastball voltage) at one or more output terminals **124**, the first voltage having a voltage level that is based on the fastball speed setting. When the changeup control module **118** is in the unengaged state, the output terminals **124** of the fastball control module **116** may be communicatively coupled to the input terminals **123** of

6

the motor **108** and the first voltage is passed to the motor **108** as the input voltage. The first voltage causes the motor **108** to rotate at the first rotary speed, thereby configuring the rotary wheel **102** to throw a fastball pitch.

When the changeup control module **118** is switched to the engaged state, the speed control module **115** may transition the input voltage from the first voltage to the second voltage. In some embodiments, the changeup control module **118** may interrupt the communicative coupling between the output terminals **124** of the fastball control module **116** and the input terminals **123** of the motor **108**. The changeup control module **118** may then couple the input terminals **123** to a resistive load (not shown). The resistive load may cause the motor **108** to convert to a generator and feed the input voltage into the resistive load. This process may also be referred to as resistive braking and/or regenerative braking. The resistive braking may cause the voltage level of the input voltage to reduce quickly. The changeup control module **118** may couple the input terminals **123** to the resistive load until the input voltage reaches a second voltage (i.e., a changeup voltage). When the input voltage reaches the second voltage, the input terminals **123** may be coupled to a follower circuit (not shown). The follower circuit may produce the second voltage, so that the input voltage is held at the second voltage. The second voltage may cause the motor **108** to rotate at the second rotational speed, thereby configuring the rotary wheel **102** to throw a changeup pitch.

The resistive braking scheme used by the changeup control module **118** may allow the rotational speed of the motor **108** to be transitioned from the first rotational speed (corresponding to a fastball pitch) to the second rotational speed (corresponding to a changeup pitch) relatively quickly. For example, the motor **108** may transition from about 2500 rpm to about 2100 rpm in about 2-3 seconds. Thus, the ball throwing machine **100** may transition from throwing a fastball pitch to a changeup pitch without increasing a delay time between pitches.

In some embodiments, the resistive load may include one or more resistors. In some embodiments in which the power source is a battery, the resistive load may include the battery. In these embodiments, the motor **108** may recharge the battery when transitioning from the first voltage to the second voltage.

When the changeup control module **118** is switched back to the unengaged state, the input terminals **123** of the motor **108** are again communicatively coupled with the output terminals **124** of the fastball control module **116**. The fastball control module **116** again feeds the first voltage to the motor **108** as the input voltage. The rotational speed of the rotary wheel **102** may ramp back up to the first rotational speed from the second rotational speed. In some embodiments, the rotary wheel **102** may ramp up to the first rotational speed according to a logarithmic function. The rotational speed of rotary wheel **102** may be substantially equal to the first rotational speed (i.e., at least 95% of the first rotational speed) prior to the next pitch.

In various embodiments, the ball throwing machine **100** may include a changeup switch **126** to toggle the changeup control module **118** between the engaged state and the unengaged state. In some embodiments, the changeup switch may be located on a handheld controller **128** communicatively coupled to the changeup control module **118**. In some embodiments, as shown in FIG. 3, the handheld controller **128** may communicate wirelessly with the changeup control module **118**. The handheld controller **128** may communicate with the changeup control module via radio

frequency (RF) signals, and/or via any suitable wireless communication protocol, such as Bluetooth, a wireless broadband network (e.g., Wi-Fi, WiMax), and/or a cellular network. The handheld controller **128** may include an antenna **130** to transmit signals to (and/or receive signals from) the changeup control module **118**, and the changeup control module **118** may include an antenna **132** to receive signals from (and/or transmit signals to) the handheld controller **128**. The changeup switch **126** may include one or more buttons, toggles, sliders, a touchscreen, and/or other suitable actuators that may be actuated to tell the handheld controller **128** to send a signal to the changeup control module **118** to tell the changeup control module to change its state (e.g., from the unengaged state to the engaged state and/or from the engaged state to the unengaged state). In some embodiments, the handheld controller **128** may be a consumer electronics device, such as a personal digital assistant (PDA), mobile phone, personal computer (PC), tablet computer, and/or mp3 player.

In other embodiments, the handheld controller **128** may communicate with the changeup control module **118** over a wired connection. In yet other embodiments, the changeup switch **126** may be coupled to the body portion **104** and/or the control box **109**.

In some embodiments, the changeup control module **118** may be selectively switched (e.g., by the handheld controller **128**) from the unengaged state to the engaged state and from the engaged state to the unengaged state. Alternatively, or additionally, the changeup control module **118** may automatically switch back to the unengaged state from the engaged state after a period of time in the engaged state. The length of the period of time may be configured to allow enough time for the ball throwing machine **100** to throw one or more changeup pitches.

In some embodiments, the ball throwing machine **100** may be configured to automatically throw a changeup periodically. Accordingly, the changeup control module **118** may be configured to automatically switch from the engaged state to the unengaged state at pre-determined and/or random intervals. This may be especially suited for automatic feed machines and allow the athlete to practice hitting fastballs and/or changeups without the presence of an operator to control the ball throwing machine **100**.

In other embodiments, the ball throwing machine may include any number of one or more rotary wheels, such as one, two, three or more rotary wheels. In some embodiments, each rotary wheel may be coupled to an associated motor. As shown in FIGS. **6** and **7**, a ball throwing machine **300** including a first rotary wheel **302** and a second rotary wheel **304**. The first rotary wheel **302** may be coupled to a first motor **306**, and the second rotary wheel **304** may be coupled to a second motor **308**. A feed structure **310** may be configured to receive a ball (not shown) and direct the ball between the outer circumferential surfaces of the first rotary wheel **302** and second rotary wheel **304**. The ball may be pinched between the outer circumferential surfaces of first rotary wheel **302** and second rotary wheel **304**, and the rotation of the rotary wheels may throw the ball forward. Accordingly, the ball throwing machine **300** may not include a pinch plate.

The first rotary wheel **302** and second rotary wheel **304** may be oriented vertically (as shown in FIGS. **6** and **7**), horizontally, and/or at an angle between vertical and horizontal. In some embodiments, the orientation of the first rotary wheel and/or second rotary wheel **304** may be adjustable between the vertical orientation and/or the horizontal orientation.

In some embodiments, the first motor **306** and second motor **308** may be controlled independently to independently control the rotational speed of the first rotary wheel **302** and/or the second rotary wheel **304**. Each motor may be coupled to a speed control module as described above. In other embodiments, the first motor **306** and second motor **308** may both be controlled by the same speed control module. The plurality of rotating wheels may be used to throw a variety of pitches including fastballs, changeups, curveballs, sinkers, risers, and/or sliders. Accordingly, the speed control module and/or changeup algorithm may be configured to control the rotational speed of one or more of the rotating wheels to throw any number of suitable pitches within the target zone.

As shown in FIGS. **8** and **9**, a ball throwing machine **400** may include a first rotary wheel **402**, a second rotary wheel **404**, and a third rotary wheel **406**, each coupled to a body portion **408**. The ball throwing machine **400** may be supported by a support structure **409** (e.g., a tripod). A first motor **410** may be coupled to the first rotary wheel **402**, a second motor **412** may be coupled to the second rotary wheel **404**, and a third motor **414** may be coupled to the third rotary wheel **406**. A feed structure **416** may be configured to receive a ball (not shown) and direct the ball between the outer circumferential surfaces of the first rotary wheel **402**, second rotary wheel **404**, and third rotary wheel **406**. The ball may be pinched between the outer circumferential surfaces, and the rotation of the rotary wheels may throw the ball forward. Accordingly, the ball throwing machine **400** may not include a pinch plate.

The first rotary wheel **402**, second rotary wheel **404**, and third rotary wheel **406** may be oriented in any suitable orientation with respect to one another. In some embodiments, the orientation of one or more of the rotary wheels may be adjustable.

In some embodiments, the first motor **410**, second motor **412**, and/or third motor **414** may be controlled independently to independently control the rotational speed of the respective rotary wheel. Each motor may be coupled to a control box **418**. The control box **418** may include a speed control module, as described above, to control the rotational speed of the first motor **410**, second motor **412**, and/or third motor **414**. In some embodiments, each motor may be controlled by a separate speed control module. In other embodiments, two or more of the first motor **410**, second motor **412** and/or third motor **414** may be controlled by the same speed control module. The plurality of rotating wheels may be used to throw a variety of pitches including fastballs, changeups, curveballs, sinkers, risers, and/or sliders. Accordingly, the speed control module and/or changeup algorithm may be configured to control the rotational speed of one or more of the rotating wheels to throw any number of suitable pitches within the target zone.

Although the ball throwing machine has been described herein as being used to throw pitches to a batter, the ball throwing machine may also be used to throw balls for other purposes, such as to practice catching, fielding (e.g., ground balls and/or fly balls), and/or other purposes. Furthermore, although the ball throwing machine has been described herein with reference to throwing baseballs and/or softballs, the ball throwing machine may be used to throw any suitable ball or other object, such as tennis balls and/or footballs. The terms changeup and fastball are not meant to be limited to baseballs and/or softballs and may be used to describe throwing any object at different relative speeds.

Although certain embodiments have been illustrated and described herein, it will be appreciated by those of ordinary

skill in the art that a wide variety of alternate and/or equivalent embodiments or implementations calculated to achieve the same purposes may be substituted for the embodiments shown and described without departing from the scope. Those with skill in the art will readily appreciate that embodiments may be implemented in a very wide variety of ways. This application is intended to cover any adaptations or variations of the embodiments discussed herein. Therefore, it is manifestly intended that embodiments be limited only by the claims and the equivalents thereof.

What is claimed is:

1. A ball throwing machine comprising:

one or more rotary wheels, all of which are disposed to simultaneously contact a ball to be thrown, the one or more rotary wheels coupled to a body portion, each rotary wheel coupled to an associated motor, the motor configured to rotate the rotary wheel at a rotational speed, the rotational speed based at least in part on a parameter of an input signal received by the motor;

a feed structure coupled to the body portion and configured to receive the ball and direct the ball to an outer circumferential surface of the one or more rotary wheels, the one or more rotary wheels configured to throw the ball outwardly from the ball throwing machine toward an athlete;

a speed control circuit coupled to at least one of the motors, the speed control circuit selectively switchable between a fastball setting and a changeup setting and configured to control the motor during the fastball setting to rotate the associated rotary wheel at a first rotational speed and to control the motor during the changeup setting to rotate the associated rotary wheel at a second rotational speed;

wherein the speed control circuit is configured to determine the second rotational speed, using a changeup algorithm, based at least in part on the first rotational speed so that the ball will arrive at the athlete in a target zone during the fastball setting and the changeup setting without adjusting a position of the one or more rotary wheels and without adjusting a position of the feed structure; and

wherein a speed difference between the first rotational speed and the second rotational speed is greater for a fastball setting associated with a relatively high speed fastball than for a fastball setting associated with a relatively low speed fastball.

2. The ball throwing machine of claim 1, wherein the speed control circuit is configured to deliver a first voltage to the motor during the fastball setting and to deliver a second voltage to the motor during the changeup setting, wherein the first voltage has a value based on a fastball speed setting of the speed control circuit, and wherein the second voltage has a value based at least in part on the value of the first voltage.

3. The ball throwing machine of claim 2, wherein the fastball speed setting is controlled by a potentiometer, the potentiometer being controllable by an operator of the ball throwing machine.

4. The ball throwing machine of claim 2, wherein the speed control circuit includes a fastball control circuit and a changeup control circuit, the fastball control circuit configured to produce the first voltage and communicatively coupled to input terminals of the motor during the fastball setting to pass the first voltage to the motor, and the changeup control circuit coupled to the fastball control circuit and configured to interrupt the communicative cou-

pling between the fastball control circuit and the input terminals of the motor during the changeup setting to transition the input voltage from the first voltage to the second voltage.

5. The ball throwing machine of claim 4, wherein the changeup control circuit is further configured to couple the input terminals of the motor to a resistive load to transition the input voltage from the first voltage to the second voltage.

6. The ball throwing machine of claim 5, wherein the changeup control circuit is further configured to, when the input voltage reaches the second voltage, couple the input terminals of the motor to a follower circuit configured to provide the second voltage.

7. The ball throwing machine of claim 1, further comprising a handheld controller configured to communicate wirelessly with the speed control circuit to selectively place the speed control circuit in the fastball setting and/or the changeup setting.

8. The ball throwing machine of claim 1, wherein the speed control circuit is configured to automatically switch to the fastball setting from the changeup setting after a time period in the changeup setting.

9. The ball throwing machine of claim 1, wherein the changeup algorithm includes a polynomial function.

10. The ball throwing machine of claim 1, wherein the motor comprises a first motor coupled to a first rotary wheel of the one or more rotary wheels, the ball throwing machine further comprising a second motor coupled to a second rotary wheel, the second motor configured to rotate the second rotary wheel at a second rotational speed based at least in part on a value of a second input signal received by the second motor, and the second rotary wheel coupled to the body portion and having an outer circumferential surface spaced from the outer circumferential surface of the first rotary wheel to throw a ball in cooperation with the first rotary wheel.

11. The ball throwing machine of claim 10, further comprising a third motor coupled to a third rotary wheel, the third motor configured to rotate the third rotary wheel at a third rotational speed based at least in part on a value of a third input signal received by the third motor, the third rotary wheel coupled to the body portion and having an outer circumferential surface spaced from the outer circumferential surfaces of the first and second rotary wheels to throw a ball in cooperation with the first and second rotary wheels.

12. The ball throwing machine of claim 1, wherein ball throwing machine is to throw the ball with a same initial trajectory when the speed control circuit is in the fastball setting and when the speed control circuit is in the changeup setting.

13. A ball throwing machine comprising:

one or more radially aligned rotary wheels coupled to a body portion, each rotary wheel coupled to an associated motor, the motor configured to rotate the rotary wheel at a rotational speed, the rotational speed based at least in part on a parameter of an input signal received by the motor;

a feed structure coupled to the body portion and configured to receive a ball and direct the ball to an outer circumferential surface of the one or more rotary wheels, the one or more rotary wheels configured to throw the ball outwardly from the ball throwing machine toward an athlete;

a speed control circuit coupled to at least one of the motors, the speed control circuit selectively switchable between a fastball setting and a changeup setting and configured to control the motor during the fastball

11

setting to rotate the associated rotary wheel at a first rotational speed and to control the motor during the changeup setting to rotate the associated rotary wheel at a second rotational speed;

wherein the speed control circuit is configured to determine the second rotational speed, using a changeup algorithm, based at least in part on the first rotational speed so that the ball will arrive at the athlete in a target zone during the fastball setting and the changeup setting without adjusting a position of the one or more rotary wheels and without adjusting a position of the feed structure; and

wherein a speed difference between the first rotational speed and the second rotational speed is greater for a fastball setting associated with a relatively high speed fastball than for a fastball setting associated with a relatively low speed fastball.

14. A ball throwing machine comprising:

- a rotary wheel coupled to a body portion;
- a motor coupled to the rotary wheel to rotate the rotary wheel at a rotational speed;
- a feed structure coupled to the body portion and configured to receive a ball and direct the ball to an outer circumferential surface of the rotary wheel, the rotary

12

wheel configured to throw the ball outwardly from the ball throwing machine toward an athlete;

- a speed control circuit coupled to the motor, the speed control circuit selectively switchable between a fastball setting and a changeup setting and configured to control the motor during the fastball setting to rotate the rotary wheel at a first rotational speed and to control the motor during the changeup setting to rotate the rotary wheel at a second rotational speed;

wherein the speed control circuit is configured to determine the second rotational speed based at least in part on the first rotational speed so that the ball will arrive at the athlete in a target zone during the fastball setting and the changeup setting without adjusting a position of the rotary wheel and without adjusting a position of the feed structure; and

wherein a speed difference between the first rotational speed and the second rotational speed is greater for a fastball setting associated with a relatively high speed fastball than for a fastball setting associated with a relatively low speed fastball.

15. The ball throwing machine of claim **14**, wherein the rotary wheel is the only rotary wheel included in the ball throwing machine.
